

Classification of the 256 key bits in the 6.75-round attack. Each block of squares is one key word k_i , with bit 31 on the left and bit 0 on the right. Gray squares are the 80 conditional PNBs, which are fixed to chosen values instead of being guessed. Red squares are the restricted bits k^{res} , the key bits on which the syncopation conditions are placed. Blue squares are the syncopated segments, the output bits of the key subtraction that no longer depend on the fixed bits below a condition once it holds. White squares are the remaining significant key bits, which the attack guesses. The two starred conditions on $k_2[14]$ and $k_9[8]$, which the paper drops because they do not improve the backward correlation, are still drawn together with their segments.
